- 5 Conclusion
- 6 Beyond Linear Programming

How can we solve $\min\{\mathbf{x} \in \mathbb{R} \mid \mathbf{x} \geq 0\}$?

Define

$$f_{\mu}(\mathbf{x}) = \mathbf{x} - \underbrace{\mu \ln(\mathbf{x})}_{\text{"barrier"}}$$

If $\mu > 0$ is small, then $f_{\mu}(\mathbf{x}) \simeq \mathbf{x}$.

We have (for $\mathbf{x} > 0$)

$$f'_{\mu}(\mathbf{x}) = 1 - \mu \frac{1}{\mathbf{x}} \quad \longrightarrow \quad f'_{\mu}(\mathbf{x}) = 0 \Leftrightarrow \mathbf{x} = \mu$$

$$f''_{\mu}(\mathbf{x}) = \frac{\mu}{\mathbf{x}^2} \quad \longrightarrow \quad f_{\mu} \text{ is convex!}$$

How can we solve

$$\begin{aligned} \min_{\mathbf{x}} \quad & 2\mathbf{x}_1 + 3\mathbf{x}_2 \\ \text{s.t.} \quad & \mathbf{x}_1 + \mathbf{x}_2 = 1, \\ & \mathbf{x}_1, \mathbf{x}_2 \geq 0 \end{aligned}$$

Barrier problem:

$$\begin{aligned} \min_{\mathbf{x}} \quad & 2\mathbf{x}_1 + 3\mathbf{x}_2 - \mu \ln \mathbf{x}_1 - \mu \ln \mathbf{x}_2 \\ \text{s.t.} \quad & \mathbf{x}_1 + \mathbf{x}_2 = 1, \end{aligned}$$

→ no easy closed-form solution!

Figure: $\mu = 1.0$

Figure: $\mu = 0.8$

Figure: $\mu = 0.5$

Figure: $\mu = 0.2$

Figure: $\mu = 0.1$

Original problem (LP)

$$\begin{aligned} \min_{\mathbf{x}} \quad & c^T \mathbf{x} \\ \text{s.t.} \quad & A\mathbf{x} = b \\ & \mathbf{x} \geq 0 \end{aligned}$$

Barrier problem (convex)

$$\begin{aligned} \min_{\mathbf{x}} \quad & c^T \mathbf{x} - \underbrace{\mu \sum_{j=1}^n \ln(x_j)}_{\text{barrier}} \\ \text{s.t.} \quad & A\mathbf{x} = b \end{aligned}$$

As μ goes to zero: the sequence of \mathbf{x}_μ defines a *central path*

Figure: Central path - examples

- 1 Foreword
- 2 The "barrier" approach
- 3 Theory of IPMs**
- 4 Linear Algebra in IPMs
- 5 Conclusion
- 6 Beyond Linear Programming

Primal-dual pair of LPs

$$\begin{aligned}
 (P) \quad & \min_{\mathbf{x}} \quad c^T \mathbf{x} \\
 & \text{s.t.} \quad A\mathbf{x} = \mathbf{b} \\
 & \quad \quad \mathbf{x} \geq 0
 \end{aligned}$$

$$\begin{aligned}
 (D) \quad & \max_{\mathbf{y}, \mathbf{s}} \quad b^T \mathbf{y} \\
 & \text{s.t.} \quad A^T \mathbf{y} + \mathbf{s} = \mathbf{c} \\
 & \quad \quad \mathbf{s} \geq 0
 \end{aligned}$$

KKT optimality conditions:

$$A\mathbf{x} = \mathbf{b} \quad [\text{primal feas.}] \quad (1)$$

$$A^T \mathbf{y} + \mathbf{s} = \mathbf{c} \quad [\text{dual feas.}] \quad (2)$$

$$\forall i, \mathbf{x}_i \cdot \mathbf{s}_i = 0 \quad [\text{slackness}] \quad (3)$$

$$\mathbf{x}, \mathbf{s} \geq 0 \quad (4)$$

Barrier problem

$$\begin{aligned} \min_{\mathbf{x}} \quad & f_{\mu}(\mathbf{x}) \\ \text{s.t.} \quad & A\mathbf{x} = b \end{aligned}$$

At the optimum: $\nabla f_{\mu}(\mathbf{x}) = c - \mu \frac{1}{\mathbf{x}} = A^T \mathbf{y}$ for some $\mathbf{y} \in \mathbb{R}^m$.
 (∇f_{μ} and gradient of constraints are linearly dependent)

Let $\mathbf{s}_j = \mu / \mathbf{x}_j$, we have

$$\begin{aligned} A\mathbf{x} &= b, \\ A^T \mathbf{y} + \mathbf{s} &= c, \\ \mathbf{x}_j \cdot \mathbf{s}_j &= \mu, \quad j = 1, \dots, n \\ \mathbf{x}, \mathbf{s} &\geq 0. \end{aligned}$$

Newton's method for solving $f(x) = 0$

Start from x_0

- $x_1 = x_0 - \frac{f(x_0)}{f'(x_0)}$
- ...
- $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$

until $f(x_n) \simeq 0$.

At each iteration:

$$0 = f(x_n) + \underbrace{(x_{n+1} - x_n)}_{\Delta x} \times f'(x_n)$$

Newton's method for solving $f(x) = e^x - 1 = 0$

Idea: apply Newton method to the KKT system (1)-(4)

$$F(\mathbf{x}, \mathbf{y}, \mathbf{s}) := \begin{bmatrix} A\mathbf{x} - b \\ A^T\mathbf{y} + \mathbf{s} - c \\ X\mathbf{S}e - \mu e \end{bmatrix}$$

so that (1)–(4) $\Leftrightarrow F(\mathbf{x}, \mathbf{y}, \mathbf{s}) = 0$.

Newton direction Δ given by

$$\underbrace{\begin{bmatrix} A & 0 & 0 \\ 0 & A^T & I \\ S & 0 & X \end{bmatrix}}_{\nabla F(\mathbf{x}, \mathbf{y}, \mathbf{s})} \cdot \underbrace{\begin{bmatrix} \Delta x \\ \Delta y \\ \Delta s \end{bmatrix}}_{\Delta} = \underbrace{\begin{bmatrix} b - A\mathbf{x} \\ c - A^T\mathbf{y} - \mathbf{s} \\ \mu e - X\mathbf{S}e \end{bmatrix}}_{-F(\mathbf{x}, \mathbf{y}, \mathbf{s})} \quad (5)$$

Affine-scaling direction (predictor) given by

$$\begin{bmatrix} A & 0 & 0 \\ 0 & A^T & I \\ S & 0 & X \end{bmatrix} \cdot \begin{bmatrix} \Delta x \\ \Delta y \\ \Delta s \end{bmatrix} = \begin{bmatrix} b - Ax \\ c - A^T y - s \\ -XS_e \end{bmatrix}$$

Centering direction towards μ -center given by

$$\begin{bmatrix} A & 0 & 0 \\ 0 & A^T & I \\ S & 0 & X \end{bmatrix} \cdot \begin{bmatrix} \Delta x \\ \Delta y \\ \Delta s \end{bmatrix} = \begin{bmatrix} b - Ax \\ c - A^T y - s \\ -XS_e + \mu e \end{bmatrix}$$

Predictor-Corrector algorithm: combine the two

- Predictor step: make progress towards optimality (decrease μ)
- Corrector step: improve centrality (stay close to central path)

Mehrotra's Predictor-Corrector algorithm [Mehrotra, 1992]

Predictor step Δ^{aff}

$$\begin{bmatrix} A & 0 & 0 \\ 0 & A^T & I \\ S & 0 & X \end{bmatrix} \cdot \begin{bmatrix} \Delta x^{aff} \\ \Delta y^{aff} \\ \Delta s^{aff} \end{bmatrix} = \begin{bmatrix} b - Ax \\ c - A^T y - s \\ -XSe \end{bmatrix}$$

Centering-corrector step Δ^{cc}

$$\begin{bmatrix} A & 0 & 0 \\ 0 & A^T & I \\ S & 0 & X \end{bmatrix} \cdot \begin{bmatrix} \Delta x^{cc} \\ \Delta y^{cc} \\ \Delta s^{cc} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \sigma \mu e - \Delta X^{aff} \Delta S^{aff} \end{bmatrix}$$

where:

$$\mu = \frac{1}{n} \mathbf{x}^T \mathbf{s}, \quad \mu^{aff} = \frac{1}{n} (\mathbf{x} + \alpha^{aff} \Delta \mathbf{x}^{aff})^T (\mathbf{s} + \alpha^{aff} \Delta \mathbf{s}^{aff}), \quad \sigma = (\mu^{aff} / \mu)^3$$

Combined direction:

$$\Delta = \Delta^{aff} + \Delta^{cc}$$

Figure: Mehrotra's Predictor-Corrector, in x space

- LP in standard **Primal-Dual** form

$$\begin{array}{ll}
 (P) & \min_{\mathbf{x}} \quad c^T \mathbf{x} \\
 & \text{s.t.} \quad A\mathbf{x} = \mathbf{b} \\
 & \quad \quad \mathbf{x} \geq 0
 \end{array}
 \qquad
 \begin{array}{ll}
 (D) & \max_{\mathbf{y}, \mathbf{s}} \quad b^T \mathbf{y} \\
 & \text{s.t.} \quad A^T \mathbf{y} + \mathbf{s} = \mathbf{c} \\
 & \quad \quad \mathbf{s} \geq 0
 \end{array}$$

- IPMs apply Newton's method to the KKT conditions

$$\begin{array}{ll}
 A\mathbf{x} = \mathbf{b}, \quad \mathbf{x} \geq 0, & \text{[primal feas.]} \\
 A^T \mathbf{y} + \mathbf{s} = \mathbf{c}, \quad \mathbf{s} \geq 0, & \text{[dual feas.]} \\
 \mathbf{x}_j \cdot \mathbf{s}_j = \mu, \quad \forall j & \text{[slackness]}
 \end{array}$$

→ solve a few linear systems

- Polynomial-time algorithm (see [Wright, 1997])
- Very efficient on large-scale problems

- 1 Foreword
- 2 The "barrier" approach
- 3 Theory of IPMs
- 4 Linear Algebra in IPMs**
- 5 Conclusion
- 6 Beyond Linear Programming

At each IPM iteration: solve a (large) linear system

$$\begin{bmatrix} 0 & A^T & I \\ A & 0 & 0 \\ S & 0 & X \end{bmatrix} \cdot \begin{bmatrix} \Delta x \\ \Delta y \\ \Delta s \end{bmatrix} = \begin{bmatrix} \xi_d \\ \xi_p \\ \xi_{xs} \end{bmatrix}$$

→ typically 60–90% of total time!

Two ways to make an Interior-Point faster:

- Reduce the number of iterations (better algorithm)
- Reduce the time per iteration (better linear algebra)

Initial Newton system:

$$\begin{bmatrix} 0 & A^T & I \\ A & 0 & 0 \\ S & 0 & X \end{bmatrix} \cdot \begin{bmatrix} \Delta x \\ \Delta y \\ \Delta s \end{bmatrix} = \begin{bmatrix} \xi_d \\ \xi_p \\ \xi_{xs} \end{bmatrix}$$

Substitute Δs to obtain the **Augmented system**

$$\begin{bmatrix} -\Theta^{-1} & A^T \\ A & 0 \end{bmatrix} \cdot \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix} = \begin{bmatrix} \xi_d - X^{-1}\xi_{xs} \\ \xi_p \end{bmatrix}$$

$$\Delta s = X^{-1}(\xi_{xs} - S\Delta x)$$

where $\Theta := XS^{-1}$

- :(Left-hand matrix is indefinite (though regularization can be used)
- :(Still costly to solve
- :) More handy if free variables and/or non-linear terms

Substitute Δx to obtain the **Normal equations**

$$(A\Theta A^T)\Delta y = \xi_p + A\Theta(\xi_d - X^{-1}\xi_{xs})$$

$$\Delta x = \Theta(A^T \Delta y - \xi_d + X^{-1}\xi_{xs})$$

$$\Delta s = X^{-1}(\xi_{xs} - S\Delta x)$$

:) $A\Theta A^T$ is symmetric positive-definite...

:(... but dense if A has dense columns

\implies We now focus on solving $(A\Theta A^T)\Delta y = \xi$

We want to solve

$$\underbrace{(A\Theta A^T)}_S \Delta y = \xi$$

S is symmetric positive definite,
we can compute its **Cholesky factorization**

$$S = L \times L^T$$

where L is lower triangular with positive diagonal.

André Cholesky (X1895)

Available libraries: SuiteSparse, MUMPS, Pardiso, etc.

Sparsity pattern of A

Sparsity pattern of S

Sparsity pattern of A

Sparsity pattern of S

One dense column in $A \implies A\Theta A^T$ is fully dense

Sparsity pattern of S Sparsity pattern of L 

Cholesky factor L has more non-zeros than $S \rightarrow$ fill-in

Linear algebra in IPMs

Newton system \longrightarrow Normal equations \longrightarrow Cholesky

- :) Numerically stable, parallelizable
- :) Readily available implementations
- :(Can consume a lot of memory

Other options:

- Exploit structure in A
- Iterative methods (e.g. conjugate gradient)

- 1 Foreword
- 2 The "barrier" approach
- 3 Theory of IPMs
- 4 Linear Algebra in IPMs
- 5 Conclusion**
- 6 Beyond Linear Programming

Hands-on: going through a barrier log

Takeaway:

- Polynomial complexity, efficient in practice
- Robust behaviour: 20 – 30 iterations, regardless of problem size
- Costly linear algebra, but well-suited to parallelism

Ongoing research:

- Warm-start [Gondzio and Gonzalez-Brevis, 2015], [Engau and Anjos, 2017]
- Mixed Integer Programming
- Parallelization [Gondzio and Grothey, 2009]

Questions?

- 1 Foreword
- 2 The "barrier" approach
- 3 Theory of IPMs
- 4 Linear Algebra in IPMs
- 5 Conclusion
- 6 Beyond Linear Programming**

Figure: Generate cut from centred point?

Figure: Central path is heavily affected by branching

(Convex) Quadratic Program:

$$\begin{aligned}
 (QP) \quad & \min_{\mathbf{x}} \quad \frac{1}{2} \mathbf{x}^T Q \mathbf{x} + c^T \mathbf{x} \\
 & s.t. \quad A \mathbf{x} = b \\
 & \quad \mathbf{x} \geq 0
 \end{aligned}$$

Augmented system for QP:

$$\begin{bmatrix} -Q - \Theta^{-1} & A^T \\ A & 0 \end{bmatrix} \cdot \begin{bmatrix} \Delta \mathbf{x} \\ \Delta \mathbf{y} \end{bmatrix} = \begin{bmatrix} \xi_d - X^{-1} \xi_{\mathbf{x}\mathbf{s}} \\ \xi_p \end{bmatrix}$$

(Convex) Non-Linear Program:

$$(NLP) \quad \min_{\mathbf{x}} \quad f(\mathbf{x}) \\ \text{s.t.} \quad g(\mathbf{x}) \leq 0$$

Augmented system for NLP:

$$\begin{bmatrix} Q(\mathbf{x}, \mathbf{y}) & A(\mathbf{x})^T \\ A(\mathbf{x}) & -ZY^{-1} \end{bmatrix} \cdot \begin{bmatrix} \Delta \mathbf{x} \\ \Delta \mathbf{y} \end{bmatrix} = \begin{bmatrix} -\nabla f(\mathbf{x}) - A(\mathbf{x})^T \mathbf{y} \\ -g(\mathbf{x}) - \mu Y^{-1} \mathbf{e} \end{bmatrix}$$

where

$$A(\mathbf{x}) = \nabla g(\mathbf{x})$$

$$Q(\mathbf{x}, \mathbf{y}) = \nabla^2 f(\mathbf{x}) + \sum_{i=1}^m \mathbf{y}_i \nabla^2 g(\mathbf{x})$$
